

(a)

slot: atomic renderings of the three relaxed
H-terminated surfaces (side + top view)
requires VESTA/OVITO -- not available here

(b)

The three H-terminated surfaces and their thickness-extrapolated surface stress. (a) is a reserved slot: rendering the relaxed structures needs VESTA or OVITO, neither of which is available in the environment that produced this figure, and (100)'s dimer rows cannot be drawn from the data files alone. (b) Each facet's τ_{xx} and τ_{yy} as the ends of a dumbbell with the mean marked; axis labels are the crystallographic directions recorded in `tau_infinity.csv`. Positive τ is COMPRESSIVE (CLAUDE.md sec 2). The asymmetry is the finding: (100) straddles zero (+1.03 to -5.02 N/m , opposite signs on the two in-plane axes), (110) sits entirely positive (+2.14 to +4.40), and (111) collapses to a point (+0.48) because C_{3v} symmetry forces its in-plane anisotropy to vanish identically. Epistemic level L2: converged in cutoff, k-points, vacuum and thickness.
